MASTERS THESIS

Graph Cut Optimisation in Image Segmentation

Author:
Ryan NAIDOO

Supervisor:
Dr. Jules-Raymond
TAPAMO

*A thesis submitted in fulfillment of the requirements
for the degree of Master of Science in Engineering*

in the

Department of Electrical, Electronic and Computer Engineering
School of Engineering

June 10, 2016

Declaration of Authorship

I, Ryan NAIDOO, declare that this thesis titled, “Graph Cut Optimisation in Image Segmentation” and the work presented in it are my own. I confirm that:

- This work was done wholly or mainly while in candidature for a research degree at this University.
- Where any part of this thesis has previously been submitted for a degree or any other qualification at this University or any other institution, this has been clearly stated.
- Where I have consulted the published work of others, this is always clearly attributed.
- Where I have quoted from the work of others, the source is always given. With the exception of such quotations, this thesis is entirely my own work.
- I have acknowledged all main sources of help.
- Where the thesis is based on work done by myself jointly with others, I have made clear exactly what was done by others and what I have contributed myself.

Chapter 1

Introduction

1.1 What is Image Segmentation

definition

types: region, edge

human segmentation -> Gestalt Groupings

Machine segmentation

Good segmentation vs Bad Segmentation

Goal of Image segmentation

Differences between bottom-up and top-down image segmentation

number of labels (2 labels -> binarization or binary segmentation, etc)

1.2 Gestalt Theory of Visual Perception

A psychological view of visual perception. The aim here is to give a brief realisation of the current understandings of human visual perception. Since image segmentation is predominantly guided by subjective human perception, it is wholesome to understand, at least briefly, what human perception is all about; at least to our current understanding.

[It would be good to get a few experts to manually segment the same images and do a similarity comparison. This will prove that even experts in the same field are subject to their own interpretation of an image. Also compare the manual segmentation to people that are not experts in the field. Discuss, how trustworthy are manual segmentations?]

Gestalt¹ - movement in experimental psychology. Developed in Germany We perceive objects as well-organised patterns rather than separate components. Gestalt is a theory that the brain operates holistically, with self-organising tendencies. "The whole is greater than the sum of its parts." Illusory Contours - The Kanisza triangle as figure ground illusory contours. Three main principles: Grouping(proximity, similarity, continuity, closure), Goodness of Figures, Figure/Ground Relationships.

Goodness of Figure, or the Law of Prägnanz².

Figure/Ground Relationships: Figure-Foreground, Ground-Background, Contours-"belong" to the Figure. Reversible Figure/Ground Relationship.

Problems with Gestalt Theory: - It is a phenomenological approach. - Some terms are vague. E.g What is the simplest organisation?

¹Gestalt is the German word mean Organised Whole

²Prägnanz is the German word for Pregnant, but in the sense of pregnant with meaning, not with child.

- principles of grouping
- contrast
- good continuity
- context
- closure
- figure and ground
- symmetry and surroundedness
- prägnanz

Contrast When perception is influenced by comparison. Three types:

Brightness Contrast

Colour Contrast

Size Contrast

Context When a stimulus can be interpreted in more than one way, the context resolves the ambiguity. Given the ambiguity of certain 2-D figures, the visual system is strongly influenced by the context within which these figures are presented. An example of Gestalt context is seen in **Figure ??**.

FIGURE 1.1: Gestalt context

Figure Ground Separation of an image into figure and ground.

Closure We tend to see figures as whole even though lines enclosing them are incomplete.

FIGURE 1.2: Gestalt Closure

Good Continuation, or Good Figure Where lines intersect, we tend to see them as continuing along their previous course, rather than suddenly changing direction. As a result we tend to decompose figures into their simplest components.

Perceptual Consistencies 4 types:

Shape Consistency: We tend to see object as holding its essential shape even though the shape of its image changes with our view of it.

Size Consistency: An object appears to retain its essential size even though its image size changes with distance.

Brightness/Lightness Consistency: Object seem to retain about the same brightness or lightness under widely differing levels of illumination.

Colour Consistency: Object appear to retain their essential colour even though illuminated by somewhat differently coloured lights.

Principles of Grouping The principles by which you recognise object as belonging to the same group. They include:

Similarity: Object are recognised as belonging to the same group when they have a similar appearance.

Colour: Object are recognised as belonging to the same group when they have a similar appearance.

Size: Object are recognised as belonging to the same group when they have a similar appearance.

Proximity: We perceive object as belonging to the same group based on their relative distances from one another.

Region: Object are recognised as belonging to the same group when they have a similar appearance.

Connectedness: Object are recognised as belonging to the same group when they have a similar appearance.

Common Fate: We perceive object as belonging to the same group when the same things are happening to them.

FIGURE 1.3: Gestalt grouping - proximity

FIGURE 1.5: Gestalt grouping - colour

FIGURE 1.6: Gestalt grouping - connectedness

FIGURE 1.7: Gestalt grouping - region

1.3 Energy Minimisation

Brief energy minimisation and what it is. Huge number of problems in vision are inference problems which can be found from energy minimisation. The relation of the concept of energy in physics is not important but useful.

Vision problems are much more complex involving hundreds or even millions of interdependant variables. Some energies precisely model the desired inference problem while some are coarse approximations. Some energies are easy to optimise while others are known to be NP-hard. Once an accurate energy and satisfying algorithm are available, the associated inference problem is essentially solved.

Many of the most important developments in computer vision began with a proposal for a better energy, better algorithm or a combination of both.

1.4 Labelling Problems

What is a labelling problem? Type of labelling problems. What is needed for a labelling problem. What is a discrete labelling problem in vision? What are the type of labels (semantic or related to geometry).

Data driven criteria - Data influences the outcome. These preferences are dereived from machine learning.

Regularisation criteria - When we explicitly prefer some kinds of labelling over others, these criteria are called regularisers. The most prominent in computer vision are spatially coherent labellings. The idea of smoothness in preference to noisy. We know from experience that object and medical data correpsonds to coherent labels more often than not - varies from application to application but has now become a rule of thumb. Because data in computer vision tends to be highly correlated in space.

1.5 Labelling Problems as Energy Minimisation

General case of expressing data-driven and regularisation criteria as concrete energy decisions.

smoothness, neighbourhood, joint probability

Markov Random Field, MAP-MRF problem

1.6 Energy Minimisation Algorithms and Special Cases

Dynamic Programming

Binary Energies with Coherence

1.7 Thesis Overview

The remainder of the thesis outline.

Chapter 2 is where we cover the mathematical foundation to Graph Cut image segmentation.

Chapter 3 is where we cover the mathematical foundation to Graph Cut image segmentation.

Chapter 4 is where we cover the mathematical foundation to Graph Cut image segmentation.

Chapter 5 is where we cover the mathematical foundation to Graph Cut image segmentation.

Chapter 6 is where we cover the mathematical foundation to Graph Cut image segmentation.

Chapter 7 is where we cover the mathematical foundation to Graph Cut image segmentation.

Chapter 8 concludes the thesis with suggestions for further work.

Chapter 2

Mathematical Background

2.1 Graph Theory and Flow Networks

In this section we cover Graph Theory and specifically Flow Networks, which is a branch of Graph Theory, which is fundamental to the understanding of image segmentation via graph cuts. With its roots in Germany where Euler tried to find the solution to the Königsberg bridge problem, graph theory has since blossomed into a rich field of Mathematics with seemingly endless amounts of application. Graph Theory is a huge topic in mathematics and can be applied to many other sciences. Graph theory is part of another more encompassing field of Mathematics known as Combinatorics. Graph theory and applications are more useful than the average person would recognise. They're used in Google Maps to find shortest routes to destinations, in Molecular Chemistry to model the structure of atoms, and the list goes on for quite a while. It is no surprise that it is also found to be useful in image segmentation.

Graph A graph G is a pair (V, E) , where V is the set of nodes/vertices and E is the set of edges consisting of pairs (u, v) where $u, v \in V$. The graph is assumed to be finite i.e. $|V| = n$ and $|E| = m$.

In an **undirected graph**, the edge (u, v) and (v, u) are not distinct. That is, they refer to the same edge. However, in a **directed graph**, the two edges are now distinct. In a directed graph with edge (u, v) , u is known as the **tail** and v is known as the **head**. In directed graphs, edges, also known as arcs, are depicted by placing arrowheads at the head of the edge. Given an edge $e = (u, v)$, u and v are said to be **incident** on e . A graph is said to be **simple** if it does not contain any self-loops. A **self-loop** is an edge with its end points being the same vertex.

Degree The degree of a vertex v is the number of edges incident on it. $deg(v) = |\{(u, v), (v, u) \in E\}|$. A self-loop counts for 2.

If a graph is directed, also known as a **digraph**, then a node v has an **in-degree** $d_{in}(v)$ and an **out-degree** $d_{out}(v)$. A digraph is said to be **balanced** if $d_{in}(v) = d_{out}(v), \forall v \in V$.

Subgraph A graph $G' = (V', E')$ is said to be a sub-graph of $G = (V, E)$, denoted as $G' \subseteq G$, if $V' \subseteq V$ and $E' \subseteq E$.

Clique A clique is a maximal subgraph.

FIGURE 2.1: Undirected weighted graph **G**. The degree of each node is shown next to the corresponding node. The graph is simple. The red box shows the vertex set, V_G , and edge set, E_G , and their corresponding norm.

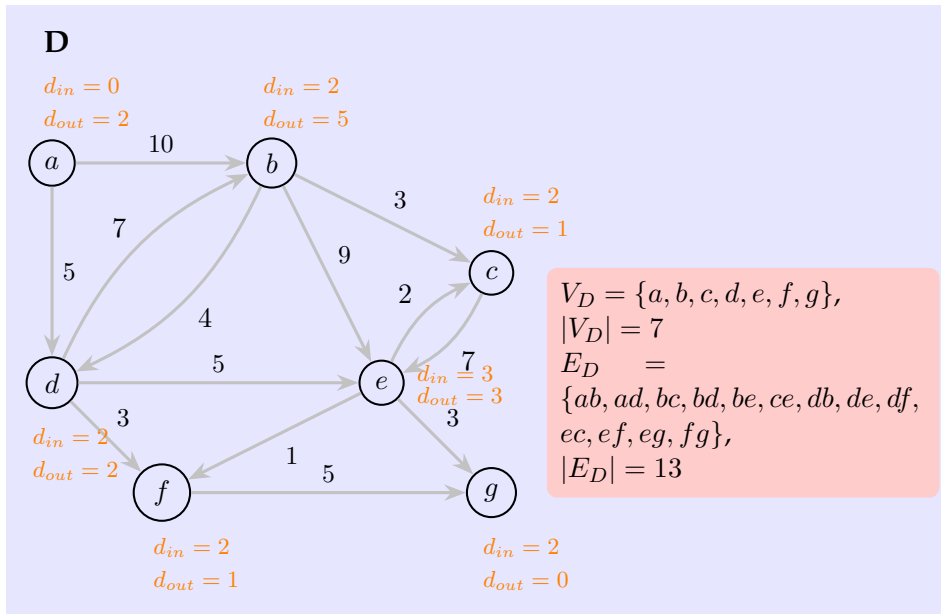

FIGURE 2.2: Directed weighted graph (Digraph) **D**. The in-degree and out-degree is shown next to each node. The graph is simple and not balanced. The red box shows the vertex set, V_D , and edge set, E_D , and their corresponding norm.

Network A network $N = (V, E)$ is a directed graph with a source node s , a sink node t and a strictly positive capacity on every edge. That is, for each edge $e \in E$, the capacity, $c(\cdot)$, obeys $c(e) \in \mathbb{R}^+$.

The **source node** only has out-going edges, $d_{in}(s) = 0$ and $d_{out}(s) \geq 0$. The **sink node** only has incoming edges, $d_{in} \geq 0$ and $d_{out} = 0$.

FIGURE 2.3: Undirected weighted graph **H** is a subgraph of **G** in Figure XX, $H \subseteq G$. Directed weighted graph **I** is a subgraph of **D** in Figure XX, $I \subseteq D$. The degree of each node is shown next to the corresponding node. The red box shows the vertex set, the edge set and their corresponding norms.

FIGURE 2.4: Network **N** with no flow. The in-degree and out-degree for the source, s , and the sink, t , are shown next to the corresponding node.

Flow A flow $f : V^2 \rightarrow \mathbb{R}^+$ is associated with each edge $e = (u, v)$ such that:

1. for each edge $e \in E$ we have $0 \leq f(e) \leq c(e)$. That is, the flow is positive and cannot exceed the capacity of the edge.
2. for each intermediate node $v \in V \setminus \{s, t\}$ the in- and out-flow of that node $\sum_{u \in V^-(v)} f(u, v) = \sum_{u \in V^+(v)} f(v, u)$.

The **total flow** F of a network is then what leave the source s or reaches the sink t :

$$F(N) := \sum_{u \in V} f(s, u) - \sum_{u \in V} f(u, s) = \sum_{u \in V} f(u, t) - \sum_{u \in V} f(t, u) \quad (2.1)$$

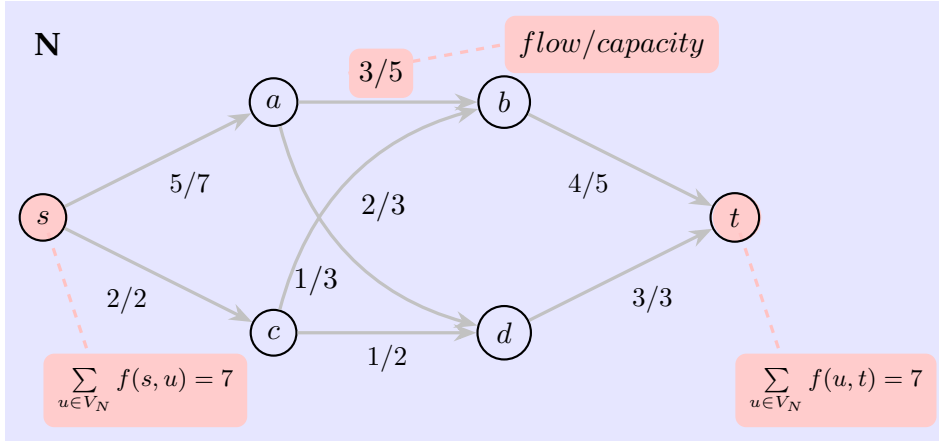

FIGURE 2.5: Network N with flow. The flow out of the source node, s , is equal to the flow into the sink node, t . For all other nodes, the flow-in is equal to the flow-out. This is the conservation of flow principle. This is only part of the network. The remaining part is the residual graph which shows the amount of reverse flow is available on an edge.

Cut A cut of a network $N = (V, E)$ is a partitioning of the vertex set $V = P \cup \bar{P}$ into two disjoint sets P containing the source node s and \bar{P} containing the sink node t . $P \cap \bar{P} = \emptyset$.

FIGURE 2.6: Network N with with a valid cut C . The nodes within the red region are reachable from the source and the nodes within the blue region are able to reach the sink. The cut set, C , is show in the orange filled block.

FIGURE 2.7: Network N with with a invalid cut C . The cut does not partition source node s and sink node t into distinct sets.

FIGURE 2.8: Network N with with a invalid cut C . The cut partition partitions the graph into more than two sets and the cut intersects the edges ab and ad twice.

The **capacity** of a cut is the sum of the edges $(u, v) \in E$ where $u \in P$ and $v \in \bar{P}$:

$$\kappa(P, \bar{P}) = \sum_{u \in P; v \in \bar{P}} c(u, v) \quad (2.2)$$

Maximal Flow The largest amount of flow that can be sent through the source that is able to reach the sink is known as the maximal flow.

Minimal Cut A cut C on a network $N = (V, E)$ is a minimal cut if there exists no other cut C' where $\kappa(C') < \kappa(C)$.

In the next section we show that the Maximal Flow problem and the Minimal Cut problem are duals of each other, commonly known as the Max-Flow/Min-Cut problem.

FIGURE 2.9: Network N with maximum flow. There is no way to push more flow out of the source into the sink without breaking the rules for conservation of flow.

FIGURE 2.10: Network N with minimal cut C . The sum of the capacity of all the edges in the cut set is the minimum of all possible valid cuts on the network N .

2.2 Markov Random Fields

In this section we review MRF's as a pure mathematical/statistical tool used specifically for vision. That is, we only cover the necessary concepts related to understanding the problem of modelling images for analysis and inference purposes. In sub-section 1 we cover the basics, in sub-section 2 we cover how to model an image using MRF, and in sub-section 3 we cover how to find the MAP, or a close enough approximation, to the MRF.

2.2.1 Markov Random Fields Theory and Concepts

MRF theory and concepts. Purely mathematical/statistical. Markov Properties

Markov Blankets

2.2.2 Markov Random Fields in Image Modelling for Segmentation

Modelling the joint probability of of image using MRFs. Nearby pixels exhibit high correlation in natural images. This is where we can take advantage of Markov Modelling.

2.2.3 MAP-MRF Approximation via Graph Cuts

How to make MAP estimates on the MRF. How does the graph-cut approach ensure an MAP solution.

2.3 Max-Flow/Min-Cut Problem

Proin accumsan, massa viverra cursus pharetra, ipsum nisi lobortis velit, a malesuada dolor lorem eu neque.

2.5.3 Push-Relabel

Originally developed by Andrew V. Goldberg and Robert E. Tarjan. Previous algorithms, such as Ford-Fulkerson, used the concept of residual networks and augmenting paths to determine max-flow. Push-Relabel used the concept of preflow to determine max-flow instead of augmenting paths. Sometimes referred as the Preflow-Push Algorithm. Preflow is a concept originally developed by A.V. Karzanov.

The algorithm works at converting a preflow, f , into a normal flow and then terminates. This flow also turns out to be the maximum flow. Goldberg and Tarjan defined a generic Push-Relabel algorithm which solves the maximum flow problem.

Preflow A preflow is a real-valued function, f , on vertex pairs. The total flow into a vertex can exceed the flow out of a vertex but not vice versa.

A preflow where all $v \in V - \{s, t\}$ has a flow excess of zero, $e_f(v) = 0$, is a normal flow. The preflow function is also referred to as the **s-t preflow**.

Preflow must satisfy:

1. Capacity Constraint
 $\forall u, v \in V, f(u, v) \leq c(u, v)$
2. Antisymmetry/Skew Symmetry
 $\forall u, v \in V, f(u, v) = -f(v, u)$
3. Nonnegative Constrain
 The flow into $v \in V - \{s\}$ must be greater than or equal to the flow out of v . $\forall u \in V, v \in V - \{s\}, \sum f(u, v) \geq 0$

Flow Excess Flow excess, $e_f(v)$, is the net flow into v where $v \in V$ for some preflow f .

$$e_f(v) = \begin{cases} \infty & \text{if } v = s \\ \sum_{u \in V} f(u, v) & \text{if } v \in V - \{s\} \end{cases}$$

Active Vertex An active vertex/node is a vertex v which satisfies all of the properties:

1. Not a source or sink, $v \in V - \{s, t\}$
2. Positive flow excess, $e_f(v) > 0$
3. Has a valid label, $d(v) < \infty$

Push-Relabel also uses the concept of a residual graph, $G_f = (V, E_f)$.

Residual Capacity The residual capacity of a preflow is defined as $r_f(v, w) = c(v, w) - f(v, w)$.

Residual Edges The residual edges for a preflow f is defined as the set of edges with positive residual capacity. $E_f = \{(v, w) | r_f(v, w) > 0\}$.

Labelling Push-Relabel also use a valid labelling function, d , to determine which vertex pairs should be selected for the push operation.

A valid labelling, d , is a nonnegative integer function applied to all vertices to denote a label. The labelling is often referred as the height or distance from the sink node, t . This function is sometimes compared to the physical intuition that liquids naturally flow downhill.

A valid labelling for a preflow consists of:

1. For $v \in V, 0 \leq d(v) \leq \infty$
2. $d(s) = |V|$ (source condition)
3. $d(t) = 0$ (sink condition)
4. $d(v) = d(w) + 1$ for every residual edge $(v, w) \in E_f$

A labelling d and a preflow f are said to be compatible if d adheres to the properties above.

The algorithm pushes flow excess starting at the source, s , along all vertices towards the sink, t . The algorithm maintains a compatible vertex labelling function, d , to the preflow, f . The labelling is used to determine where to push the flow excess. The algorithm repeatedly performs either a push or a relabel operation so long as there is an active vertex in G_f .

Push Operation The push operation is used to move flow from one vertex to another. The transfer of excess can be performed across the vertex pair $(v, w) \in E_f$ if:

1. v is an active vertex
2. the edge has positive residual capacity, $r_f(v, w) > 0$
3. the label distance $d(v) = d(w) + 1$

This allows the algorithm to move δ excess flow: $\delta = \min(e_f(v), r_f(v, w))$ from v to w . A push is considered **saturating** if no more flow can be sent over the edge, $\delta = r_f(v, w)$. A push is considered to be **non-saturating** if all the excess from v is pushed over the edge and the edge still has some capacity, $\delta = e_f(v)$.

Algorithm 2 Push Operation

Input: Preflow f , labels d , and (v, w) where $v, w \in V$

Output: Preflow f

Applicable: if $v \in V - \{s, t\}$, $d(v) < \infty$, $e_f(v) > 0$, $r_f(v, w) > 0$ and $d(v) = d(w) + 1$

- 1: **procedure** PUSH(v, w)
 - 2: $\delta := \min(e_f(v), r_f(v, w))$
 - 3: $f(v, w) := f(v, w) + \delta$
 - 4: $f(w, v) := f(w, v) - \delta$
 - 5: $e_f(v) := e_f(v) - \delta$
 - 6: $e_f(w) := e_f(w) + \delta$
 - 7: **return** f
 - 8: **end procedure**
-

Relabel Operation The relabel operation is used to increase the label value of a single active vertex so that excess flow can be pushed out of the active vertex. The relabel operation is performed when all the residual edges of the active vertex have positive residual capacity, $r_f(v, w) > 0$. This implies that v 's label is less than or equal to all vertices, $d(v) \leq d(w)$, meaning that no push operation across the edges is possible given the push condition $d(v) = d(w) + 1$.

The relabel operation for some vertex v selects the smallest label for the vertices with positive residual edges, $r_f(v, w) > 0$. The active vertex is then assigned the smallest label value $+1$ such that $d(v) := \min d(w) + 1 \mid (v, w) \in E_f$. This will allow the vertex v to potentially push its excess flow to atleast one of the othe vertices during the algorithm's next iteration.

Algorithm 3 Relabel Operation

Input: Preflow f , labels d , and $v \in V - \{s, t\}$

Output: Labels d

Applicable: if $v \in V - \{s, t\}$, $d(v) < \infty$, $e_f(v) > 0$, and $\forall w \in V, r_f(v, w) > 0$ which implies $d(v) \leq d(w)$

```

1: procedure RELABEL( $v$ )
2:   if  $\{(v, w) \in E_f\} \neq \emptyset$  then
3:      $d(v) := \min(d(w) + 1 \mid (v, w) \in E_f)$ 
4:   else
5:      $d(v) := \infty$ 
6:   end if
7:   return  $d$ 
8: end procedure

```

The algorithm initialises the following values in the residual graph before the push and relabel operations in the main loop.

1. Initialise the preflow of all edges in the residual graph
2. Initialise the labellings such that:
 - (a) $d(s) = |V|$
 - (b) $d(v) = 0$ for $v \in V - \{s\}$
3. Performs saturation, pushes along all residual edges out of the source $(s, v) \in E_f$ and $v \in V$.

Once complete the algorithm repeatedly performs either a push or a relabel operation against all vertices. The algorithm continues until no operation can be performed. The algorithm terminates when there are no more active vertices.

The analysis and the proof of correctness of the Push-Relabel algorithm can be found in [Appendix B](#).

Push-Relabel Speed Optimisation Heuristics

Discharge Push-Relabel also use a valid labelling function d , to determine which vertex pairs should be selected for the push operation.

FIFO Push-Relabel also use a valid labelling function d , to determine which vertex pairs should be selected for the push operation.

Highest Label First Push-Relabel also use a valid labelling function d , to determine which vertex pairs should be selected for the push operation.

Global Relabel Push-Relabel also use a valid labelling function d , to determine which vertex pairs should be selected for the push operation.

Gap Relabel Push-Relabel also use a valid labelling function d , to determine which vertex pairs should be selected for the push operation.

Algorithm 4 Push-Relabel Main-loop

Input: Network flow graph $G = (V, E)$, s, t and c **Output:** Maximum flow f

```

1: procedure MAIN( $v$ )
2:   for all  $(v, w) \in (V - \{s\})(V - \{s\})$  do
3:      $f(v, w) := 0$ 
4:      $f(w, v) := 0$ 
5:   end for

6:   for all  $v \in V$  do
7:      $f(s, v) := r_f(s, v)$ 
8:      $f(v, s) := -r_f(s, v)$ 
9:   end for

10:   $d(s) = |V|$ 

11:  for all  $v \in V - \{s\}$  do
12:     $d(v) := 0$ 
13:     $e_f(v) := f(s, v)$ 
14:  end for

15:  While there exists an active vertex
16:    while  $\exists v \in V - \{s, t\}$  do ▷ with either applicable PUSH() or
      RELABEL() operation
17:      Perform either a PUSH or a RELABEL operation on  $v$ 
18:    end while

19:  return  $f$ 
20: end procedure

```
